# gurobipy Course

Xavier.nodet @ gurobi.com

October 2025 - 6fe312c

Latest update of the course, slides and exercises

https://nodet.github.io

Gurobi can solve models with linear and quadratic (incl. nonconvex) constraints and objective.

minimize 
$$x^TQx + c^Tx + d$$
  
subject to  $Ax = b$   

$$x^TQ_ix + c_i^Tx \le d_i \qquad \forall i \in I$$

$$l \le x \le u$$

$$x_j \in \mathbb{Z} \qquad \forall j \in J$$

And nonlinear constraints as well!

# 1. Introductory examples

Let us start with a simple example

maximize 
$$x + y + 2z$$
  
subject to  $x + 2y + 3z \le 4$   
 $x + y \ge 1$   
 $x, y, z \in \{0, 1\}$ 

### Here is the Python code to solve this problem:

```
import gurobipy as gp
from gurobipy import GRB
with gp.Env() as env, gp.Model("simple-example", env=env) as model:
    x = model.addVar(vtype=GRB.BINARY, name="x")
    y = model.addVar(vtype=GRB.BINARY, name="y")
    z = model.addVar(vtype=GRB.BINARY, name="z")
    model.addConstr(x + 2 * y + 3 * z \le 4, name="c0")
                                                                        (5)
   model.addConstr(x + y >= 1, name="c1")
   model.setObjective(x + y + 2 * z, sense=GRB.MAXIMIZE)
                                                                        (6)
   model.write("example.lp")
```

- <sup>①</sup>Import gurobipy package as gp for convenience
- <sup>2</sup> GRB is the list of all Gurobi constants
- <sup>®</sup> Create a Gurobi environment and a model object
- <sup>4</sup> Define decision variables
- <sup>5</sup> Define constraints
- <sup>©</sup> Define objective

- <sup>⑦</sup> Save the model as an LP file
- <sup>®</sup>Optimize model
- <sup>®</sup>X attribute is the variable's value in the solution

# Here is the log of the execution of this program:

```
Gurobi Optimizer version 12.0.3 build v12.0.3rc0 (mac64[arm] - Darwin 24.6.0
24G231)
CPU model: Apple M4 Pro
Thread count: 12 physical cores, 12 logical processors, using up to 12 threads
Optimize a model with 2 rows, 3 columns and 5 nonzeros
Model fingerprint: 0x98886187
Variable types: 0 continuous, 3 integer (3 binary)
Coefficient statistics:
 Matrix range [1e+00, 3e+00]
 Objective range [1e+00, 2e+00]
  Bounds range [1e+00, 1e+00]
  RHS range [1e+00, 4e+00]
```

```
Found heuristic solution: objective 2.0000000
Presolve removed 2 rows and 3 columns
Presolve time: 0.00s
Presolve: All rows and columns removed
Explored 0 nodes (0 simplex iterations) in 0.00 seconds (0.00 work units)
Thread count was 1 (of 12 available processors)
Solution count 2: 3 2
Optimal solution found (tolerance 1.00e-04)
Best objective 3.00000000000e+00, best bound 3.0000000000e+00, gap 0.0000%
***** Solution ******
x: 1.0
y: 0.0
z: 1.0
```

\*\*\*\*\*\*\*

# And here's the generated LP file:

```
\ Model simple-example
\ LP format - for model browsing. Use MPS format to capture full model detail.
Maximize
 x + y + 2z
Subject To
 c0: x + 2 y + 3 z <= 4
 c1: x + y >= 1
Bounds
Binaries
X Y Z
End
```

### The same example, using the matrix API

```
import gurobipy as gp
from gurobipy import GRB
import numpy as np
import scipy.sparse as sp
with gp.Env() as env, gp.Model("matrix1", env=env) as m:
   # Create variables
    x = m.addMVar(shape=3, vtype=GRB.BINARY, name="x")
    # Set objective
    obj = np.array([1.0, 1.0, 2.0])
    m.setObjective(obj @ x, GRB.MAXIMIZE)
```

```
# Build (sparse) constraint matrix
row = np.array([0, 0, 0, 1, 1])
col = np.array([0, 1, 2, 0, 1])
val = np.array([1.0, 2.0, 3.0, -1.0, -1.0])
# A is such that A[row[k], col[k]] = val[k]
A = sp.csr matrix((val, (row, col)), shape=(2, 3))
# Build rhs vector
rhs = np.array([4.0, -1.0])
# Add constraints
m.addConstr(A @ x <= rhs, name="c")</pre>
# Write the model
m.write("matrix1.lp")
# Optimize model
```

```
m.optimize()

print(x.X)

print(f"Obj: {m.ObjVal:g}")
```

#### Here's the log of the execution:

```
Gurobi Optimizer version 12.0.3 build v12.0.3rc0 (mac64[arm] - Darwin 24.6.0
24G231)
CPU model: Apple M4 Pro
Thread count: 12 physical cores, 12 logical processors, using up to 12 threads
Optimize a model with 2 rows, 3 columns and 5 nonzeros

 c[1]: -x[0] - x[1] <= -1
Bounds
Binaries
x[0] x[1] x[2]
End
```

# 2. Python Data Structures

• tuple: An ordered, compound grouping that cannot be modified once it is created and is ideal for representing multi dimensional subscripts.

```
("city_0", "city_1")
```

• list: An ordered group, so each item is indexed. Lists can be modified by adding, deleting or sorting elements.

```
["city_0", "city_1", "city_2"]
```

• set: An unordered group of unique elements. Sets can only be modified by adding or deleting.

```
{"city_0", "city_1", "city_2"}
```

• dict: A key-value pair mapping that is ideal for representing indexed data such as cost, demand, capacity.

```
demand = {"city_0": 100, "city_1": 50, "city_2": 40}
```

# 3. Extended Data Structures in gurobipy

# 3.1. tuplelist

tuplelist: a sub-class of Python list, used to build sub-lists efficiently. See in particular tuplelist.select(pattern).

```
<gurobi.tuplelist (2 tuples, 3 values each):
  ( A , B , C )
  ( A , E , C )
>
```

## 3.2. tupledict

tupledict: a sub-class of Python dict, where the values are usually Gurobi variables, to efficiently retrieve those whose key match a specified tuple pattern.

Some important methods to build linear expressions efficiently:

- tupledict.select(pattern) → list
- tupledict.sum(pattern) → gp.LinExpr
- tupledict.prod(coeff, pattern) → gp.LinExpr

```
import gurobipy as gp
m = gp.Model()
x = m.addVars([(1,2), (1,3), (2,3)], name="x")  # x is a tupledict
coeff = dict([((1,2), 2.0), ((1,3), 2.1), ((2,3), 3.3)])
m.update()  # Process all model updates
print(x.sum('*', 3))
print(x.prod(coeff))
print(x.prod(coeff, '*', 3))
```

```
x[1,3] + x[2,3]
2.0 x[1,2] + 2.1 x[1,3] + 3.3 x[2,3]
2.1 x[1,3] + 3.3 x[2,3]
```

### 3.3. multidict()

multidict() is a convenience function to split a dict of lists.

```
import gurobipy as gp
keys, dict1, dict2 = gp.multidict( {
   'key1': [1, 2],
   'key2': [1, 3],
   'key3': [1, 4] } )
print(keys)
print(dict1)
print(dict2)
```

```
['key1', 'key2', 'key3']
{'key1': 1, 'key2': 1, 'key3': 1}
{'key1': 2, 'key2': 3, 'key3': 4}
```

#### 3.4. Example of extended structures

```
data: {('a', 'b', 'c'): 3, ('a', 'c', 'b'): 4, ('b', 'a', 'c'): 5, ('b', 'c', 'a'): 6, ('c', 'a', 'b'): 7, ('c', 'b', 'a'): 3}
```

```
print("\nTuplelist:")
keys = gp.tuplelist(data.keys())
print(f"\tselect: {keys.select('a', '*', '*')}")
```

```
Tuplelist:
    select: <gurobi.tuplelist (2 tuples, 3 values each):
    ( a , b , c )
    ( a , c , b )
>
```

```
print("\nTupledict:")
print(f"\tselect : {data.select('a', '*', '*')}")
print(f"\tsum : {data.sum('*', '*', '*')}")
coeff = {("a", "c", "b"): 6, ("b", "c", "a"): -4}
print(f"\tprod : {data.prod(coeff, '*', 'c', '*')}")
```

```
Tupledict:
    select : [3, 4]
    sum : 28.0
    prod : 0.0
```

```
arcs, capacity, cost = gp.multidict({
        ("Detroit ", "Boston "): [100, 7],
        ("Detroit ", "New York "): [80, 5],
        ("Detroit ", "Seattle "): [120, 4],
        ("Denver ", "Boston "): [120, 8],
        ("Denver ", "New York "): [120, 11],
        ("Denver ", "Seattle "): [120, 4],
    })
print("\nMultidict:")
print(f"\tcapacity: {capacity}")
print("\n")
print(f"\tcost: {cost}")
```

```
Multidict:
    capacity: {('Detroit ', 'Boston '): 100, ('Detroit ', 'New York '): 80,
    ('Detroit ', 'Seattle '): 120, ('Denver ', 'Boston '): 120, ('Denver ', 'New
York '): 120, ('Denver ', 'Seattle '): 120}

cost: {('Detroit ', 'Boston '): 7, ('Detroit ', 'New York '): 5, ('Detroit
', 'Seattle '): 4, ('Denver ', 'Boston '): 8, ('Denver ', 'New York '): 11,
    ('Denver ', 'Seattle '): 4}
```

#### 4. Environments

Environments hold data that is global to one or more models.

- They hold a Gurobi license.
- They capture sets of parameter settings.
- They delineate a (single-threaded) Gurobi session.

## The basic usage pattern is the following:

```
import gurobipy as gp
from gurobipy import GRB

with gp.Env() as env, gp.Model("name", env=env) as m:
    # Use the model
...
```

### A more advanced usage pattern is:

```
import gurobipy as gp
from gurobipy import GRB
with gp.Env(empty=True) as env:
    # Set licensing parameters
    env.setParam("CloudAccessID", "...")
    env.setParam("CloudSecretKey", "...")
    env.setParam("LicenseID", ...)
    # Start the environment before creating a model
    env.start()
    with gp.Model("name", env=env) as m:
        # Use the model
        . . .
```

# 5. Models

A model holds:

- variables
- constraints
- parameters, that define the behavior of the solver

```
with gp.Env() as env, gp.Model("simple-example", env=env) as model:
    x = model.addVar(vtype=GRB.BINARY, name="x")
    y = model.addVar(vtype=GRB.BINARY, name="y")
    c1 = model.addConstr(x + y >= 1, name="c1")
   model.setObjective(x + y + 2 * z, sense=GRB.MAXIMIZE)
   model.params.MipFocus=1
    model.params.TimeLimit = 3600
   model.optimize()
```

- <sup>10</sup> Focus on finding the best possible solutions
- <sup>2</sup> Stop after one hour

It has methods to create and edit variables and constraints, to set parameters, to solve the model, to retrieve information, and more.

```
# ...
model.write("model.mps")
model.chgCoeff(c1, x, 2)
model.computeIIS()

①
②
```

- <sup>10</sup> Store the model in an MPS file
- <sup>2</sup> Change the coefficient of variable x in constraint c1 to 2
- <sup>3</sup> Compute an Irreducible Inconsistent Set

## 5.1. Decision Variables, Model.addVar()

A decision variable is necessarily associated to exactly one instance of Model, and gets created using methods such as Model.addVar() to create a single variable, Model.addVars() to create multiple variables at once and Model.addMVars() to create a matrix of variables.

```
Model.addVar(lb=0.0, ub=float('inf'),
        obj=0.0,
        vtype=GRB.CONTINUOUS,
        name="")
```

## The available variable types in Gurobi are:

- Continuous: GRB.CONTINUOUS
- General integer: GRB.INTEGER
- Binary: GRB.BINARY
- Semi-continuous: GRB.SEMICONT
- Semi-integer: GRB.SEMIINT

A semi-continuous variable has the property that it takes a value of 0, or a value between the specified lower and upper bounds. A semi-integer variable adds the additional restriction that the variable should take an integral value.

```
# Define a binary decision variable with (default) lb=0
x = model.addVar(vtype=GRB.BINARY, name="x")
# Define an integer variable with lb=-1, ub=100
y = model.addVar(lb=-1, ub=100, vtype=GRB.INTEGER, name="y")
```

#### 5.2. Model.addVars()

To add multiple decision variables to the model, use the Model.addVars() method which returns a Gurobi tupledict object containing the newly created variables:

The first argument is an iterable giving indices for accessing the variables:

- several integers (specifying the dimensions of the matrix)
- several lists of scalars (each list specifies indices across one dimension of the matrix)
- one list of tuples, or a tuplelist

When the given name is a single string, it is subscripted by the index of the generator expression. The names are stored as ASCII strings, you should not use non-ASCII characters or spaces.

```
import gurobipy as gp
from gurobipy import GRB

with gp.Model(name="model") as model:
    # 3D array of binary variables
    x = model.addVars(2, 3, 4, vtype=GRB.BINARY, name="x")
    model.update()
    print(model.getAttr("VarName", model.getVars()))
```

```
['x[0,0,0]', 'x[0,0,1]', 'x[0,0,2]', 'x[0,0,3]', 'x[0,1,0]', 'x[0,1,1]', 'x[0,1,2]', 'x[0,1,3]', 'x[0,2,0]', 'x[0,2,1]', 'x[0,2,2]', 'x[1,0,0]', 'x[1,0,1]', 'x[1,0,2]', 'x[1,0,3]', 'x[1,1,0]', 'x[1,1,1]', 'x[1,1,2]', 'x[1,1,3]', 'x[1,2,0]', 'x[1,2,1]', 'x[1,2,2]', 'x[1,2,3]']
```

```
import gurobipy as gp
from gurobipy import GRB
with qp.Model(name="model") as model:
   # Use arbitrary lists of immutable objects -> tupledict
    y = model.addVars([1, 5], [7, 3, 2], ub=range(6),
                      name=[f"y_{i}" for i in range(6)])
   model.update()
    print("\nVariables names, upper bounds, and indices:")
    for index, var in y.items():
        print(f"name: {var.VarName}, ub: {var.UB}, index: {index}")
```

```
Variables names, upper bounds, and indices:
name: y_0, ub: 0.0, index: (1, 7)
name: y_1, ub: 1.0, index: (1, 3)
name: y_2, ub: 2.0, index: (1, 2)
```

name: y\_3, ub: 3.0, index: (5, 7)
name: y\_4, ub: 4.0, index: (5, 3)
name: y\_5, ub: 5.0, index: (5, 2)

```
import gurobipy as gp
from gurobipy import GRB
with qp.Model(name="model") as model:
    # Use arbitrary list of tuples as indices
    z = model.addVars(
        [(3, "a"), (3, "b"), (7, "b"), (7, "c")], name="z",
   model.update()
    print("\nVariables names and lower and upper bounds:")
    for index, var in z.items():
        print(f"name: {var.VarName}, lb: {var.LB}, ub: {var.UB}")
```

```
Variables names and lower and upper bounds:
name: z[3,a], lb: 0.0, ub: inf
name: z[3,b], lb: 0.0, ub: inf
```

name: z[7,b], lb: 0.0, ub: inf name: z[7,c], lb: 0.0, ub: inf

### 5.3. Constraints, Model.addConstr()

Like variables, constraints are also associated with a model. Use the method Model.addConstr() to add a constraint to a model.

```
Model.addConstr(constr, name="")
```

constr is a TempConstr object that can take different types:

- Linear Constraint: x + y <= 1</li>
- Ranged Linear Constraint: x + y == [1, 3]
- Quadratic Constraint: x\*x + y\*y + x\*y <= 1</li>
- Linear Matrix Constraint: A @ x <= 1</li>
- Quadratic Matrix Constraint: x @ Q @ y <= 2</li>
- Absolute Value Constraint: x == abs\_(y)
- Logical Constraint: x == and\_(y, z)
- Min or Max Constraint: z == max\_(x, y, constant=9)
- Indicator Constraint:  $(x == 1) \gg (y + z <= 5)$

```
import gurobipy as gp
from gurobipy import GRB
# Add constraint "\sum_{i=0}^{n-1} x_i \le b" for any given n and b.
n, b = 10, 4
with gp.Model("model") as model:
    x = model.addVars(n, vtype=GRB.BINARY, name="x")
    c1 = model.addConstr(x.sum() <= b, name="c1")</pre>
    model.update()
    print(f"RHS, sense = {c1.RHS}, {c1.Sense}")
    print(f"row: {model.getRow(c1)}")
```

```
RHS, sense = 4.0, < row: x[0] + x[1] + x[2] + x[3] + x[4] + x[5] + x[6] + x[7] + x[8] + x[9]
```

```
import gurobipy as gp
from gurobipy import GRB
# Add constraints x_i + y_j - x_i * y_j >= 3.
n, m = 3, 2
with gp.Model("model") as model:
    x = model.addVars(n, name="x")
    y = model.addVars(m, name="y")
    for i in range(n):
        for j in range(m):
            model.addConstr(x[i] + y[j] - x[i] * y[j] >= 3, name=f"c_{i}{j}")
    model.update()
    for c in model.getQConstrs():
        print(f"Name: {c.QCName}, RHS: {c.QCRHS}, sense: {c.QCSense}")
        print(f"\trow: {model.getQCRow(c)}")
```

```
Name: c 00, RHS: 3.0, sense: >
    row: x[0] + y[0] + [-1.0 x[0] * y[0]]
Name: c_01, RHS: 3.0, sense: >
    row: x[0] + y[1] + [-1.0 x[0] * y[1]]
Name: c 10, RHS: 3.0, sense: >
    row: x[1] + y[0] + [-1.0 x[1] * y[0]]
Name: c_11, RHS: 3.0, sense: >
    row: x[1] + y[1] + [-1.0 x[1] * y[1]]
Name: c 20, RHS: 3.0, sense: >
    row: x[2] + y[0] + [-1.0 x[2] * y[0]]
Name: c 21, RHS: 3.0, sense: >
    row: x[2] + y[1] + [-1.0 x[2] * y[1]]
```

#### 5.4. Model.addConstrs()

To add multiple constraints to the model, use the Model.addConstrs() method which returns a Gurobi tupledict that contains the newly created constraints:

```
Model.addConstrs(generator, name="")
```

```
import gurobipy as gp
from gurobipy import GRB
I = range(2)
J = ["a", "b", "c"]
with gp.Model("model") as model:
    x = model.addVars(I, name="x")
    y = model.addVars(J, name="y")
    # Add constraints x_i + y_j <= 1 for all (i, j)
    model.addConstrs((x[i] + y[j] <= 1 for i in I for j in J), name="c")
    model.update()
    print(model.getAttr("ConstrName", model.getConstrs()))
```

```
['c[0,a]', 'c[0,b]', 'c[0,c]', 'c[1,a]', 'c[1,b]', 'c[1,c]']
```

# 5.5. Objective Function

To set the model objective equal to a linear or a quadratic expression, use the Model.setObjective() method:

```
Model.setObjective(expr, sense=GRB.MINIMIZE)
```

## expr can be:

- LinExpr, a linear expression
- QuadExpr, a quadratic expression

sense is either GRB.MINIMIZE (the default) or GRB.MAXIMIZE.

```
import gurobipy as gp
from gurobipy import GRB
import numpy as np
# Add linear objectives c^Tx
n = 4
c = np.random.rand(n)
with gp.Model("model") as model:
    x = model.addVars(n, name="x")
    linexpr = gp.quicksum(c_i * x_i for c_i, x_i in zip(c, x.values()))
    model.setObjective(linexpr)
    model.update()
    print(f"obj: {model.getObjective()}")
```

```
obj: 0.11997409032263406 x[0] + 0.8017517174254414 x[1] + 0.2375341249729569 x[2] + 0.782034008692409 x[3]
```

```
import gurobipy as gp
from gurobipy import GRB
import numpy as np
n = 4
Q = np.random.rand(n, n)
with gp.Model("model") as model:
    x = model.addVars(n, name="x")
    quadexpr = 0
    # Add quadratic objective in the form x^T Q x
    for i in range(n):
        for j in range(n):
            quadexpr += x[i] * Q[i, j] * x[j]
    model.setObjective(quadexpr)
```

```
model.update()

# Print objective expression
obj = model.getObjective()
print(f"\nobj: {obj}")
```

```
obj: 0.0 + [ 0.4266149959241946 x[0] ^ 2 + 0.8111915623222672 x[0] * x[1] + 1.329147558943664 x[0] * x[2] + 1.047794617821438 x[0] * x[3] + 0.34113782394316683 x[1] ^ 2 + 0.6697317498705988 x[1] * x[2] + 0.7924592496844742 x[1] * x[3] + 0.3729595364579176 x[2] ^ 2 + 0.8271703191178871 x[2] * x[3] + 0.8714290199488662 x[3] ^ 2 ]
```

# 5.6. Optimizing for Multiple Objectives

Gurobi supports two ways to combine multiple linear objectives:

- Blended objectives.
- Hierarchical objectives.

## Objectives have:

- priorities
- weights
- absolute and relative tolerances

```
setObjectiveN(expr, index, priority=0, weight=1, abstol=1e-6, reltol=0, name='')
```

```
# Primary objective: x + 2 y
model.setObjectiveN(x + 2*y, 0, priority=0)

# Alternative, lower priority objectives: 3 y + z and x + z
model.setObjectiveN(3*y + z, 1, priority=-1)
model.setObjectiveN(x + z, 2, priority=-2)
```

#### 5.7. SOS Constraints

A Special-Ordered Set, or SOS constraint, is a highly specialized constraint that places restrictions on the values that variables in a given list can take.

- SOS constraint of type 1 (SOS1): at most one variable is allowed to take a non-zero value.
- SOS constraint of type 2 (SOS2): at most two variables are allowed to take non-zero values, and those non-zero variables must be contiguous.

## Use Model.addSOS() to add such constraints:

```
Model.addSOS(type, vars)
```

#### With:

- type: the type of SOS constraint. Can be either GRB.SOS\_TYPE1 or GRB.SOS\_TYPE2.
- vars: list of variables that participate in the consstraint.

For example, the MIP formulation of

$$z = max(x, y, 3)$$

using SOS1 constraints, is:

$$z = x + s_{1}$$
 (1)  

$$z = y + s_{2}$$
 (2)  

$$z = 3 + s_{3}$$
 (3)  

$$v_{1} + v_{2} + v_{3} = 1$$
 (4)  

$$SOS1(s_{1}, v_{1})$$
 (5)  

$$SOS1(s_{2}, v_{2})$$
 (6)  

$$SOS1(s_{3}, v_{3})$$
 (7)  

$$s_{1}, s_{2}, s_{3} \in \mathbb{R}^{+}$$
 (8)  

$$v_{1}, v_{2}, v_{3} \in \{0, 1\}$$
 (9)

#### 5.8. General Constraints

General constraints allow you to directly model complex relationships between variables.

• Simple constraints: min, max, abs, OR, etc.

```
m.addConstr(z == gp.and_(x, y))
m.addConstr(z == gp.max_(x, y, 3))
```

• Nonlinear constraints: polynomial, exponential, logistic, trigonometric, etc

```
model.addGenConstrNL(y, nlfunc.sin(2.5 * x1) + x2)
```

```
import gurobipy as gp
from gurobipy import nlfunc
# Minimize sin(2.5 x1) + x2
\# s.t. -1 <= x1, x2 <= 1
with gp.Env() as env, gp.Model(env=env) as model:
    x1 = model.addVar(lb=-1, ub=1, name="x1")
    x2 = model.addVar(lb=-1, ub=1, name="x2")
    y = model.addVar(lb=-float("inf"), name="y")
    model.addGenConstrNL(y, nlfunc.sin(2.5 * x1) + x2)
    model.setObjective(y)
    model.optimize()
    print(f"x1={x1.X} x2={x2.X} obj={y.X}")
```

```

## 6. Matrix-based API

- Term-based modeling can be slow
- Matrix-friendly API leans on Numpy concepts (vectorization, broadcasting)
- Model.addMVar(): Add an MVar object to a model. An MVar acts like a NumPy ndarray of Gurobi decision variables. An MVar can have an arbitrary number of dimensions, defined by the shape argument.

```
addMVar(shape, lb=0.0, ub=float('inf'), obj=0.0, vtype=GRB.CONTINUOUS, name='')

# A vector of 3 continuous variables
v = model.addMVar(3)

# A 5x10 matrix of binary variables
x = model.addMVar((5,10), vtype=GRB.BINARY)
```

# Here's the example from the beginning of the course:

```
x = m.addMVar(shape=3, vtype=GRB.BINARY, name="x")
val = np.array([1.0, 2.0, 3.0, -1.0, -1.0])
row = np.array([0, 0, 0, 1, 1])
col = np.array([0, 1, 2, 0, 1])
A = sp.csr_matrix((val, (row, col)), shape=(2, 3))
                                                      (2)
rhs = np.array([4.0, -1.0])
m.addConstr(A @ x <= rhs, name="c")</pre>
obj = np.array([1.0, 1.0, 2.0])
m.setObjective(obj @ x, GRB.MAXIMIZE)
                                                      (5)
```

## <sup>1</sup> Create variables

- <sup>2</sup> Build a (sparse) matrix
- <sup>3</sup> Build an rhs vector
- <sup>4</sup> Add constraints
- <sup>⑤</sup> Set objective

# Here is another with timing of the difference.

```
import gurobipy as gp
import numpy as np
from timeit import default_timer
n = 1000
Q = np.random.rand(n, n)
def term_based():
    with gp.Model("term-based") as model:
        x = model.addVars(n, name="x")
        model.addConstr(
            gp.quicksum(x[i] * Q[i, j] * x[j] for j in range(n)
                                                for i in range(n)) <= 10</pre>
```

```
def matrix api():
    with gp.Model("matrix-based") as model:
        x = model.addMVar(n, name="x")
        model.addConstr(x.T @ Q @ x <= 10)</pre>
matrix api() # To create the default env
for f in [term_based, matrix_api]:
    start = default timer()
    f()
    end = default timer()
    print(f"Running {f. name } took {end - start} seconds")
```

Running term\_based took 3.1411980830016546 seconds Running matrix\_api took 0.073522040998796 seconds

## 6.1. Broadcasting

MVar objects follow the NumPy broadcasting rules. These rules govern how matrices of various dimensions interact with other matrices, and what the shape of the result is.

```
X = model.addMVar((2, 3), name="X")
Y = model.addMVar((3,), name="Y")
print(X / Y)
```

```
<MNLExpr (2, 3)>
array([[ X[0,0] / Y[0], X[0,1] / Y[1], X[0,2] / Y[2]],
       [ X[1,0] / Y[0], X[1,1] / Y[1], X[1,2] / Y[2]]])
```

## Here is another example.

```
X = model.addMVar((2, 3, 4), name="X")
Y = model.addMVar((3, 1), name="Y")
print((X * Y).shape)
(2, 3, 4)
```

# Nonlinear functions are applied element-wise.

```
nlfunc.exp(X)

<MNLExpr (2, 3)>
array([[ exp(X[0,0]), exp(X[0,1]), exp(X[0,2])],
```

```
[ exp(X[1,0]), exp(X[1,1]), exp(X[1,2])]])
```

Note: If nda is a NumPy 1D array of shape (n,), nda[:, None] reshapes it to (n, 1) to enable broadcasting.

```
nda = np.array(...)
vars = m.addMVar(...)
m.addConstr((nda[:, None] * vars).sum() >= ...)
```

If vars is a (n,m) matrix and nda is of shape (n,), then the product of nda[:,None] and that matrix will be of shape (n,m).

# 7. Interacting with the Model

#### 7.1. Attributes

The primary mechanism for querying and modifying properties of a Gurobi object is through the attribute interface. Attributes exist on instances of Model, Variable, all types of constraints, and more.

#### Model:

- number of modeling elements of each type (NumConstrs, NumVars, etc.)
- information about the type of model (IsMip, IsMultiObj, etc.), its statistics (SolCount, NodeCount, etc.)
- information about the solutions found (SolCount), the best known bound (ObjBound), the gap (MipGap), etc.

• ...

### Variables:

- lower (LB) and upper (UB) bounds
- value in a MIP start vector (Start)
- value in the best solution (X)

•

## **Constraints:**

- right-hand side value (RHS)
- dual value in the best solution (Pi)

• ..

```
import gurobipy as gp
from gurobipy import GRB
with gp.read("data/glass4.mps.bz2") as model:
   model.optimize()
   print(f"\tStatus : {model.Status}")
   print(f"\t0bj : {model.0bjVal}")
   print(f"\tSolutionCount: {model.SolCount}")
   print(f"\tRuntime : {model.Runtime}")
   print(f"\tMIPGap : {model.MIPGap}")
   print("\n")
   for var in model.getVars()[:20]:
      print(f"\t{var.VarName} = {var.X}")
```

```
Read MPS format model from file data/glass4.mps.bz2
Reading time = 0.03 seconds
glass4: 396 rows, 322 columns, 1815 nonzeros
Gurobi Optimizer version 12.0.3 build v12.0.3rc0 (mac64[arm] - Darwin 24.6.0

#### 7.3. Callbacks

A callback is a user-defined function invoked by Gurobi while the optimization process is going on. They enable more control over the optimization. They can be used to:

- customize the termination of the solve
- add user cuts and lazy constraints
- add custom feasible solutions
- monitor the progress of optimization
- customize the optimization progress display

A callback must be a function (actually, any callable object) that accepts two arguments:

- model: the model that is being solved
- where: from where is the Gurobi Optimizer is the callback invoked (presolve, simplex, barrier, MIP, at a node, etc.)

A callback can query information from the solver using Model.cbGet(). The type of information that can be queried depends on from where the callback is invoked. For example, when where == PRESOLVE, you can query the number of rows removed using what == PRE\_ROWDEL. All the callback code values

# that you can query are listed here.

```
import gurobipy as gp
from gurobipy import GRB
from functools import partial
# Used by the callback to store or retrieve information
class CallbackData:
    def __init__(self):
        self.invocations = 0
# The callback, the function that will be invoked
def mycallback(model, where, *, cbdata):
    # We're only interested in this case
    if where == GRB.Callback.MIP:
        chdata.invocations += 1
```

```
# Get information from the model
        nodecnt = model.cbGet(GRB.Callback.MIP NODCNT)
        if nodecnt > 100:
            # Terminate the search
            model.terminate()
# Create a model from an instance file
with gp.read("data/glass4.mps.bz2") as model:
    # Create the object to store/retrieve information
    cbdata = CallbackData()
    # Create a callable with two args: model and where
    callback_func = partial(mycallback, cbdata=cbdata)
    # Optimize, with the callback
    model.optimize(callback func)
```

```
# Confirm the callback was invoked
print(f"MIP Callback was invoked {cbdata.invocations} times.")
```

```
Read MPS format model from file data/glass4.mps.bz2

User-callback calls 600, time in user-callback 0.00 sec MIP Callback was invoked 117 times.

#### Other methods of interest are:

- Model.cbGetNodeRel(): retrieve the values of the variables in the node relaxation solution at the current node.
- Model.cbGetSolution(): retrieve the values of the variables in the new MIP solution.
- Model.cbCut(): add a new cutting plane to the model.
- Model.cbLazy(): add a new lazy constraint to the model.
- Model.cbSetSolution(): import a user-constructed solution into Gurobi.

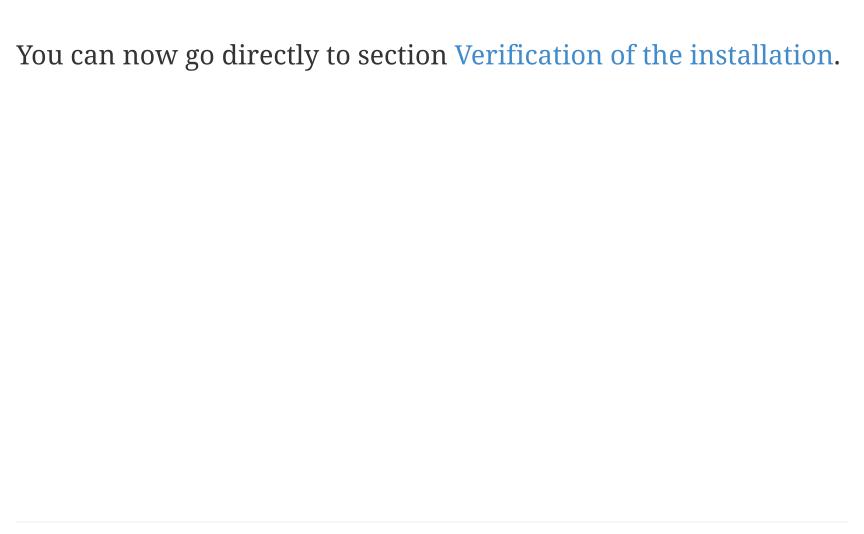

# 8. Requirements and installation

## 8.1. Setup for Windows

#### 8.1.1. Check for Anaconda 3.9 to 3.13

If you have Anaconda Python installed and this is version 3.9, 3.10, 3.11, 3.12 or 3.13, run the following commands in an Anaconda prompt.

```
conda create -n gurobipy-course python=3.13 conda activate gurobipy-course conda install -c gurobi gurobipy
```

### 8.1.2. Check for the py launcher

Check whether you already have a 'core' Python version installed:

open a Command Prompt and run

```
py --list
```

• If py --list tells you that you have version 3.9, 3.10, 3.11, 3.12 or 3.13, you can go ahead to the Installation of Gurobipy section below.

## • If you get

'py' is not recognized as an internal or external command, operable program or batch file.

then you need to install Python 3.13, as per the next section.

### **8.1.3. Install Python 3.13**

If you have none of 3.9, 3.10, 3.11, 3.12 or 3.13, install the latest 3.13 Python version from <a href="https://www.python.org/downloads/windows/">https://www.python.org/downloads/windows/</a>.

- Download the 'Windows installer (64-bit)', unless you have an ARM machine
- Run the installer (you don't need to do it as an Administrator)
- Make sure that 'Add Python 3.13 to the path' is NOT checked (so that your access to your existing Python version is not changed)

open a Command Prompt and run

py --list

• Verify that you have 3.13 listed

For more details on the installation process, refer to https://docs.python.org/3.13/using/windows.html.

#### 8.1.4. Create a venv and activate it

The reason to create a venv is to fix the Python version and isolate the work done in the venv to make sure it doesn't impact the rest of your system.

• In a Command Prompt, run

```
md gurobipy-course
cd gurobipy-course
py -3.13 -m venv venv --prompt "gurobipy-course"
```

Now that the venv has been created, you can activate it with one of the commands below. Note that you should always do this in

any new Command Prompt window that you start.

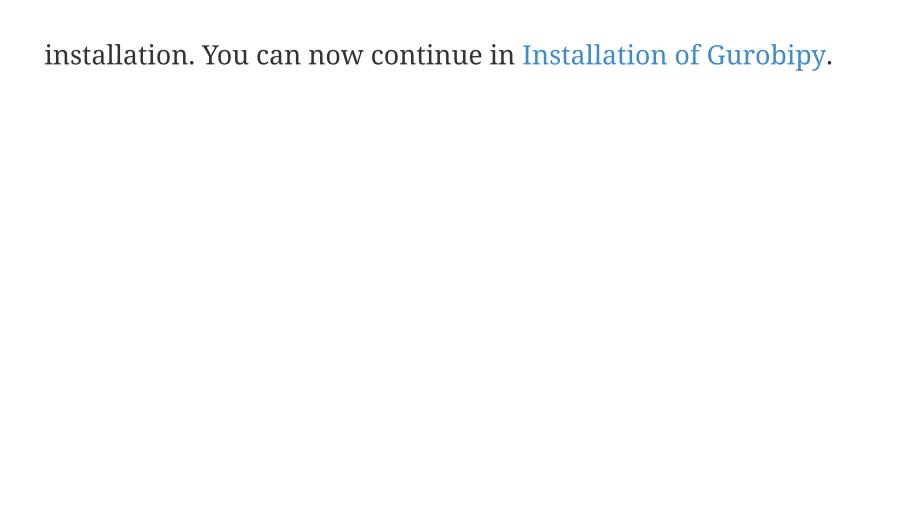

If you use PowerShell (e.g. your prompt starts with PS C:...>), use

```
.\venv\Scripts\Activate.ps1
```

If you use cmd (no PS at the start of your prompt), use

```
venv\Scripts\activate
```

After activation of a virtual environment, python and pip in that window refer to that environment, not the default system-wide

## 8.2. Setup for macOS

I will assume here that you have already installed Homebrew. Otherwise, follow the instructions there.

Install pyenv and Python 3.13

brew install pyenv pyenv install 3.13

Create a local directory for the course.

mkdir gurobipy-course
cd gurobipy-course

Configure pyenv to use Python 3.13 when in this directory.

```
pyenv local 3.13
```

Create a virtual environment for the course and activate it. From now on, remember to always activate your venv in whatever shell you use.

```
python -m venv venv --prompt "gurobipy-course"
source venv/bin/activate
```

I also highly recommend that you set the variable PIP\_REQUIRE\_VIRTUALENV=true in your environment. This forces pip

to fail when not running in a virtual environment.

## 8.3. Installation of Gurobipy

Confirm that your venv is active: you should see that your prompt is modified to mention 'gurobipy-course'. With your venv activated, confirm that

python --version

runs Python 3.13

You can now run

pip install gurobipy

### 8.4. Verification of the installation

You can check that gurobipy is correctly installed by running

```
python -c "import gurobipy as gp; m = gp.Model(); print(gp.GRB.VERSION_MAJOR)"
```

This should output one or a few lines about your license, then the Gurobi version number, which should be 12 at this time. An example could be:

```
Restricted license - for non-production use only - expires 2026-11-23
```

### 8.5. Get a free Gurobi license

- Using your academic email address, create an account on https://portal.gurobi.com.
- From a computer that belongs to your University, log onto https://portal.gurobi.com/iam/licenses/request?type=academic and request a 'WLS Academic' license
- Once you see your license at https://portal.gurobi.com/iam/licenses/list, open https://license.gurobi.com/manager/licenses/, click 'Download' at the bottom of the license card, give a name and a description to the API key that you're about to create.

- When the 'API key created' dialog appears, click the 'Download' button and save the 'gurobi.lic' file.
- Copy that file to your laptop, in your user profile folder (typically C:\Users\[name])
- Verify that running

```
python -c "import gurobipy as gp; m = gp.Model()"
```

does **not** give you any more the 'Restricted license' message.

For more details, refer to this page.
